Generating Random Variables

2.1 Generating Discrete Random Variables

Main component of a simulation study is the ability to generate random number, where a random number represents the value of random variable uniform distribution on (0,1).

2.1.1 Pseudorandom Number Generation

Random numbers were originally either manually or mechanically generated, by using spinning wheels or dice rolling or card shuffling but the modern approach is to use a computer to successively generate pseudorandom numbers.

One of the common approaches to generate pseudorandom numbers starts with an initial value x_0 , called seed, and then recursively computes successive values $x_n, n \ge 1$, by letting

$$x_n = ax_{n-1} \text{ modulo } m \tag{2.1}$$

where a and m are given positive integers, and where the equation (2.1) means that ax_{n-1} is divided by m and remainder is taken as the value of x_n . Thus, each value of x_n is either $0, 1, \ldots, m-1$ and the quantity x_n/m is pseudorandom number and follows an approximation to the value of a uniform (0,1) random variable.

The approach specified by equation (2.1) to generate random numbers is called the Multiplicative Congruential Method.

Another method is

$$x_n = (ax_{n-1} + c) \text{ modulo } m$$

this method is known as Mixed Congruential Generators where c is a non-negative integer.

2.1.2 The Inverse Transform Method

Suppose we want to generate the value of a discrete random variable X having probability mass function

$$P(X = x_i) = p_i, i = 0, 1, \dots, \sum_i p_i = 1$$

To do this, we generate a random number from a uniform distribution (0,1) U, and set

$$X = \begin{cases} x_0 & \text{if } U < p_0 \\ x_1 & \text{if } p_0 \le U \le p_0 + p_1 \\ \vdots \\ x_j & \text{if } \sum_{i=0}^{j-1} p_i \le U \le \sum_{i=0}^{j} p_i \\ \vdots \end{cases}$$

Since, for 0 < a < b < 1, $P(a \le U < b) = b - a$, we have,

$$P(X = x_j) = P\left(\sum_{i=0}^{j-1} p_i \le U < \sum_{i=0}^{j} p_i\right) = p_j.$$

So, X has the desired distribution.

Example 2.1.1 (Bernoulli Distribution). Let, $X \sim Ber(p)$ where p is success probability i.e. P(X = 0) = 1 - p and P(X = 1) = p and $0 \le p \le 1$. Then, to generate X we first generate $U \sim U[0, 1]$ then, we set

$$X = \begin{cases} 1, & \text{if } U \le p \\ 0, & \text{if } U > p \end{cases}$$

Hence, X follows Bernoulli Distribution with the parameter p.

Algorithm for Inverse Transform Algorithm for Generating Bernoulli Distribution:

STEP 1: Generate a random variable $U \sim U[0, 1]$.

STEP 2: If $U \leq p$ set X = 1 or set X = 0.

STEP 3: Go to STEP 1.

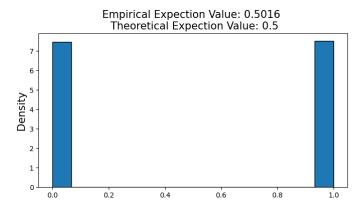

Figure 2.1: Inverse Transform plot for generating Bernoulli random numbers with p = 0.5

Example 2.1.2 (Binomial Distribution). Let, $X \sim Bin(n,p)$ then, X has probability mass function

$$f(r) = P(X = r) = \binom{n}{r} p^r (1-p)^{n-r}, \ i = 1, 2, \dots$$

The generation of $X \sim Bin(n,p)$ by Inverse Transform Algorithm can be tedious. We can use the relation between Binomial and Bernoulli distribution. If $x_i \sim Ber(p), \forall i = 1, 2, ..., n$ then, $\sum_{i=1}^{n} x_i \sim Bin(n,p)$.

Hence, by generating x_i n independent random variable from Bernoulli distribution and summing them we get binomial distribution

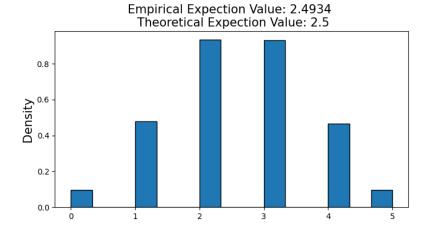

Figure 2.2: Generation of binomial random numbers with n = 5 and p = 0.5

2.2 Generating Continuous Random Variables

2.2.1 The Inverse Transform Algorithm

To generate Continuous random variables The Inverse Transform Algorithm is very important method. It is based on a following theorem.

Theorem 2.2.1. Let U be a uniform (0,1) random variable. For any continuous distribution function F the random variable X defined by

$$X = F^{-1}(U)$$

 $has\ distribution\ F.$

Proof. Let, F_X denote the distribution function of $X = F^{-1}(U)$. Then,

$$F_X(x) = P(X \le x)$$
$$= P(F^{-1}(U) \le x)$$

Since, F is a cumulative distribution function it follows that F(x) is monotonic increasing function of x and range of F(x) is (0,1). Then,

$$F_X(x) = P\left(F\left(F^{-1}(U)\right) \le F(x)\right)$$
$$= P(U \le F(x))$$
$$= F(x) \text{ since } U \sim U(0, 1)$$

The above theory tells us we can generate a random variable X from the continuous distribution function F by generating a random number $U \sim U(0,1)$ and setting $X = F^{-1}(U)$.

Example 2.2.1 (Exponentian Distribution). Suppose we want to generate a random variable $x \sim Exp(\lambda)$, then its probability density function is

$$f(x) = \lambda e^{-\lambda x}.$$

Hence, The cumulative distribution function is,

$$F(x) = 1 - e^{\lambda x}$$

if we let $x = F^{-1}(u)$, then,

$$u = F(x) = 1 - e^{-\lambda x}$$
$$1 - u = e^{-\lambda x}$$
$$x = -\frac{\ln(1 - u)}{\lambda}$$

Hence, we can generate an exponential random variable with parameter 1 by generating a uniform (0,1) random number U and then setting

$$X = F^{-1}(U) = -\frac{\ln(1-U)}{\lambda}.$$

We see that if $U \sim U(0,1)$ then also $1-U \sim U(0,1)$ thus $\ln(1-U)$ has the same distribution as $\ln(U)$ so,

$$X = F^{-1}(U) = -\frac{\ln(U)}{\lambda}.$$

will also work. If we use second expression then the algorithm will take less computing power hence less time.

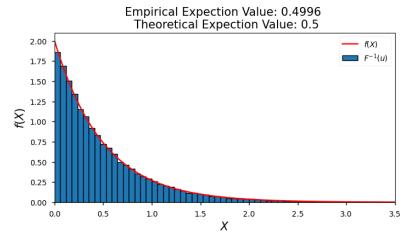

Figure 2.3: Inverse Transform plot for generating Exp(2)

Example 2.2.2 (Gamma Distribution). Let $X \sim G(n, \lambda)$ Then, its probability mass function is given by,

$$f(x) = \frac{1}{\Gamma(n)} \lambda^n x^{n-1} e^{-\lambda x}$$

We know if $X_i \sim Exp(\lambda) \forall i=1,2,\ldots,n$ then $\sum_i X_i \sim G(n,\lambda)$. Then, Generating n $X_i \sim Exp(\lambda)$ and summing them we can easily generate a random variable which follows gamma distribution
